1.0 Groundwater Management Area 2

Groundwater Management Area 2 is one of sixteen groundwater management areas in Texas and covers a large portion of the southern plains portion of west Texas (Figure 1).

Figure 1. Groundwater Management Area 2

Groundwater Management Area 2 covers all or part of the following counties: Andrews, Bailey, Borden, Briscoe, Castro, Cochran, Crosby, Dawson, Deaf Smith, Floyd, Gaines, Garza, Hale, Hockley, Howard, Lamb, Lubbock, Lynn, Martin, Parmer, Swisher, Terry, and Yoakum (Figure 2).

**Explanatory Report for Desired Future Conditions *(Final)*

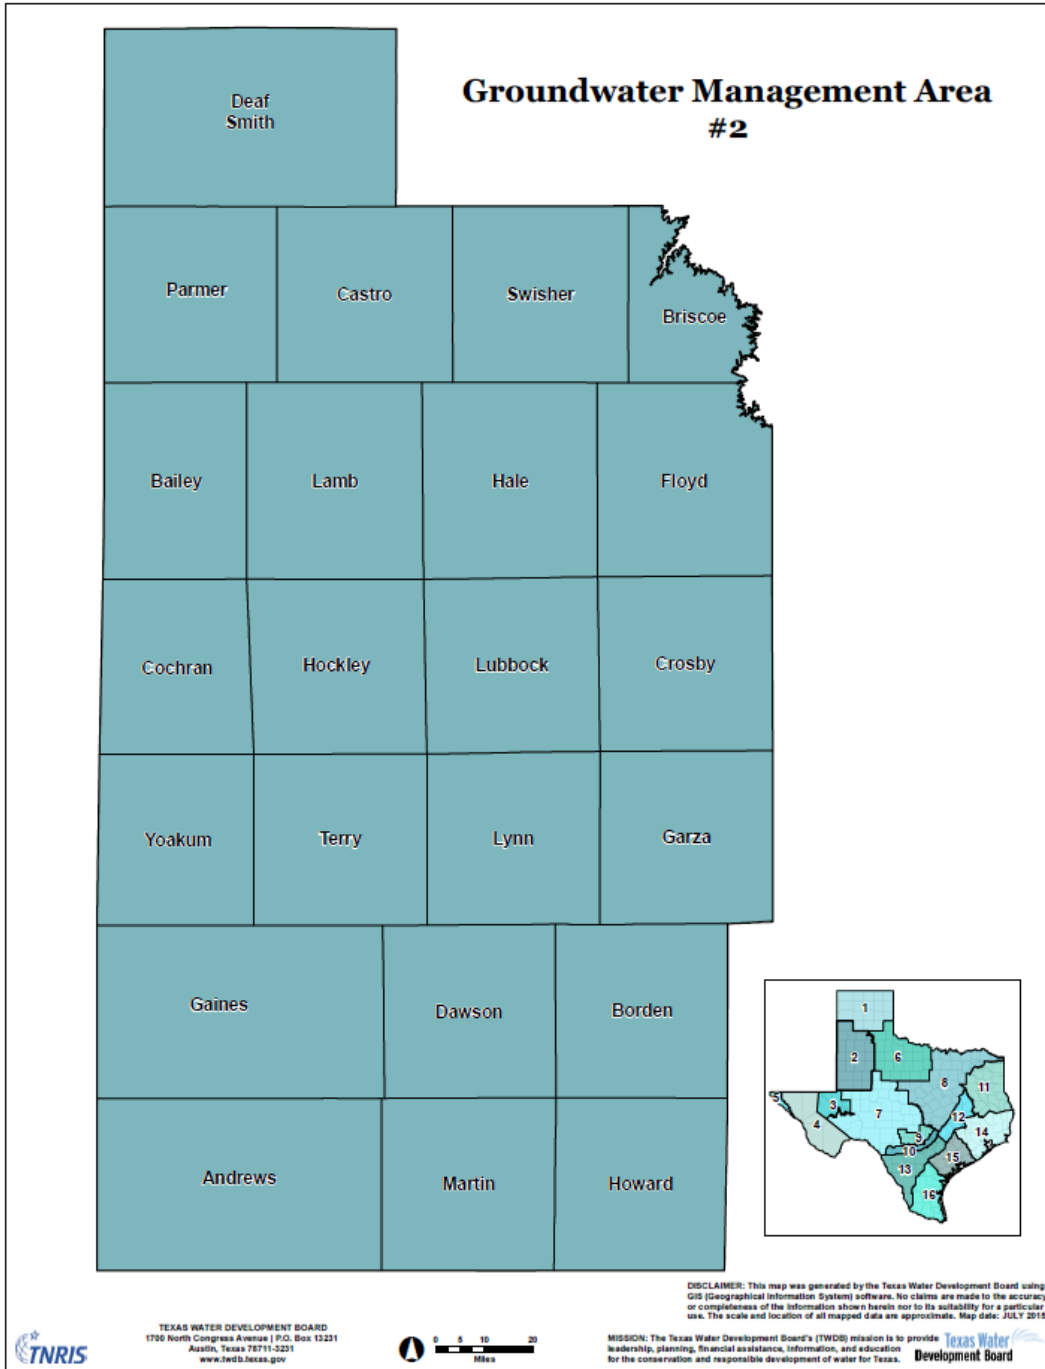

Figure 2. GMA 2 Counties (from TWDB)

There are seven groundwater conservation districts in Groundwater Management Area 2: Garza UWCD, High Plains UWCD No. 1, Llano Estacado UWCD, Mesa UWCD, Permian Basin, UWCD, Sandy Land UWCD, and South Plains UWCD.

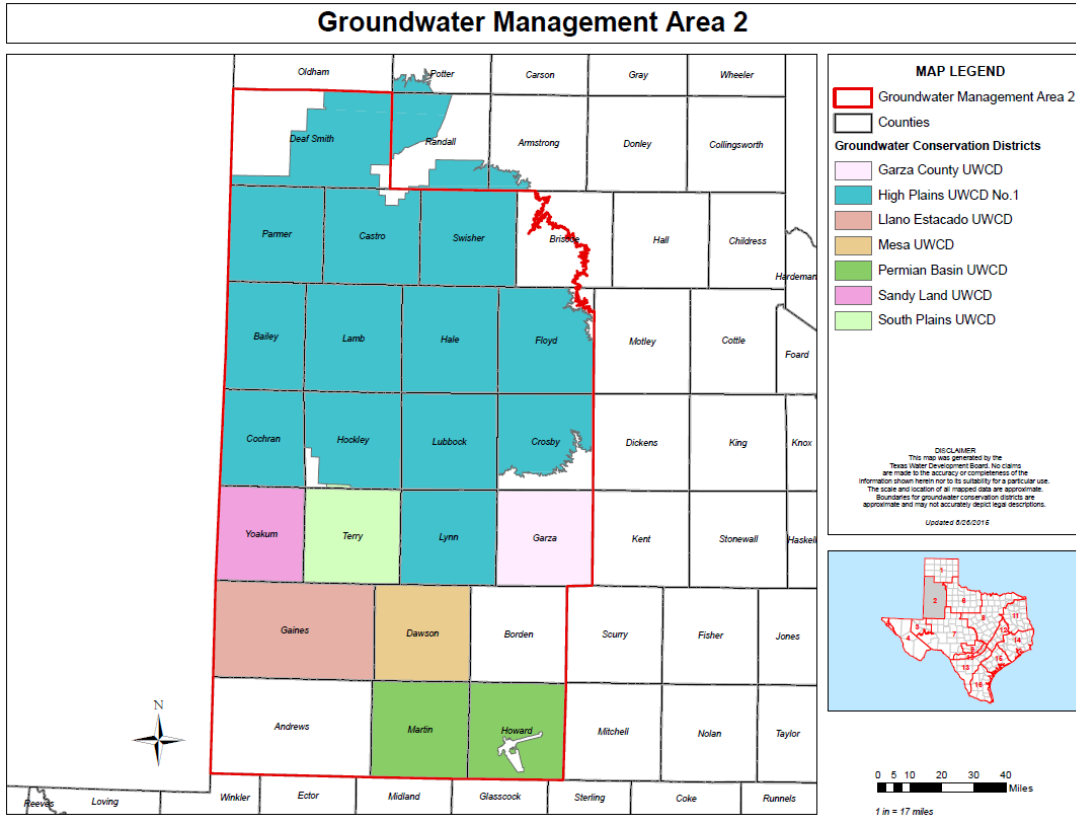

Figure 3. Groundwater Conservation Districts in GMA 2 (from TWDB)

2.0 Proposed Desired Future Condition

2.1 Background

In GMA 2, the Ogallala Aquifer, and the underlying Edwards-Trinity (High Plains) Aquifer are managed as a single unit. Historic pumping has caused groundwater level declines to the point that individual well pumping rates in many areas of the Ogallala Aquifer have been reduced. In the future, pumping is expected to continue primarily for irrigation, and pumping rates will continue to decline as groundwater levels drop further. Water conservation techniques and irrigation technologies have advanced over the years and are expected to improve in the future to mitigate the economic effects of reduced well production.

In GMA 2, groundwater from the Dockum Aquifer has been pumped in relatively small amounts, largely due to poor water quality. However, increased pumping from the Dockum Aquifer is expected in the future as envisioned in the 2021 Initially Prepared Llano Estacado Regional Water Plan (i.e. Region O Plan0).

**Explanatory Report for Desired Future Conditions *(Final)*
Ogallala, Edwards-Trinity (High Plains), and Dockum Aquifers for Groundwater Management Area 2**

The Texas Water Code and the Texas Water Development Board require that desired future conditions be a quantified condition of the aquifer in the future. The desired future condition cannot be expressed in terms of how much can be pumped from an aquifer. In GMA 2, the continued declines in groundwater levels in the Ogallala Aquifer will result in reductions in pumping rates. Thus, the drawdown that will occur in the future and the pumping rates that will decline in the future are linked.

Once a desired future condition is adopted by the groundwater conservation districts in GMA 2, the Texas Water Development Board will use the groundwater availability model to estimate the pumping that will achieve the desired future condition, or the modeled available groundwater (MAG).

2.2 2010 Desired Future Conditions

In 2010, GMA 2 adopted desired future conditions for the Ogallala and Edwards-Trinity (High Plains) aquifers that reflected the concept of managed decline of groundwater levels. In the High Plains UWCD area, the DFC was 50 percent of storage remaining after 50 years (50/50), and in the other areas of GMA 2, the DFC was expressed as a decadal decline rate.

Simulations with the Groundwater Availability Model were used at the time to develop the 2010 desired future condition. In the High Plains UWCD area, simulated pumping was adjusted in the GAM simulations to hit 50 percent storage remaining in each county of the district. Although this approach treated every county within the district equally, it ignored the inherent variability of the aquifer in terms of saturated thickness and hydraulic conductivity. Future pumping in some High Plains UWCD counties was reduced to match the 50/50 goal, while other High Plains UWCD counties had artificial increases in simulated pumping above historic amounts simply to reach the 50/50 goal.

The adopted DFC in 2010 within High Plains UWCD could be viewed as somewhat arbitrary in that a specific reduction in groundwater levels was selected without the ability to fully understand the relationship between declining groundwater levels and reduced pumping rates. The decision to adopt these DFCs was, to a degree, based on the limitations of the Groundwater Availability Model that was then used. The DFC was also based on a concept where equality in outcome was a higher consideration than a management approach that first considered the hydraulic characteristics of the aquifer, the hydraulics of pumping wells in an unconfined aquifer where groundwater levels are dropping, and the associated economics of pumping groundwater for irrigation in an area where groundwater levels are dropping.

2.3 2016 Desired Future Conditions

2.3.1 Ogallala and Edwards-Trinity (High Plains)

On October 19, 2016, the groundwater conservation districts in Groundwater Management Area 2 adopted the desired future condition for the Ogallala and Edwards-Trinity (High Plains) aquifers.

Explanatory Report for Desired Future Conditions *(Final)*
Ogallala, Edwards-Trinity (High Plains), and Dockum Aquifers for Groundwater Management Area 2

The desired future condition was expressed as an average drawdown of between 23 and 27 feet for all of GMA 2. The drawdown is calculated from the end of 2012 conditions to the year 2070.

The drawdown was expressed as a range due to the link between future pumping and future rainfall. As documented in GMA 2 Technical Memorandum 15-01 and GMA 2 Technical Memorandum 16-01, historic pumping is higher in dry years than in wet years. Since most of the water use in GMA 2 from the Ogallala Aquifer is for irrigation, producers pump more groundwater in dry years than in normal or wet years. The simulations assumed that initial pumping rates in the future would be between 100 percent and 150 percent of 2012 pumping rates. Essentially, in average or wet years, initial annual pumping would be approximately the same as 2012 pumping rates. In dry years, initial annual pumping rates could be as high as 150 percent of 2012 pumping rates based on the variation of pumping rates in the recent past.

Figure 4 presents the pumping results from the simulation for Scenario 8 from GMA 2 Technical Memorandum 15-01, and Scenario 16 from GMA 2 Technical Memorandum 16-01, and Figure 5 presents the drawdown associated with Scenarios 8 and 16. Scenario 8 assumes initial future pumping rates are 100 percent of 2012 pumping rates (average and wet conditions), and Scenario 10 assumes initial future pumping rates are 150 percent of 2012 pumping rates (dry conditions). Please note that by about 2045, the total pumping is expected to be about the same.

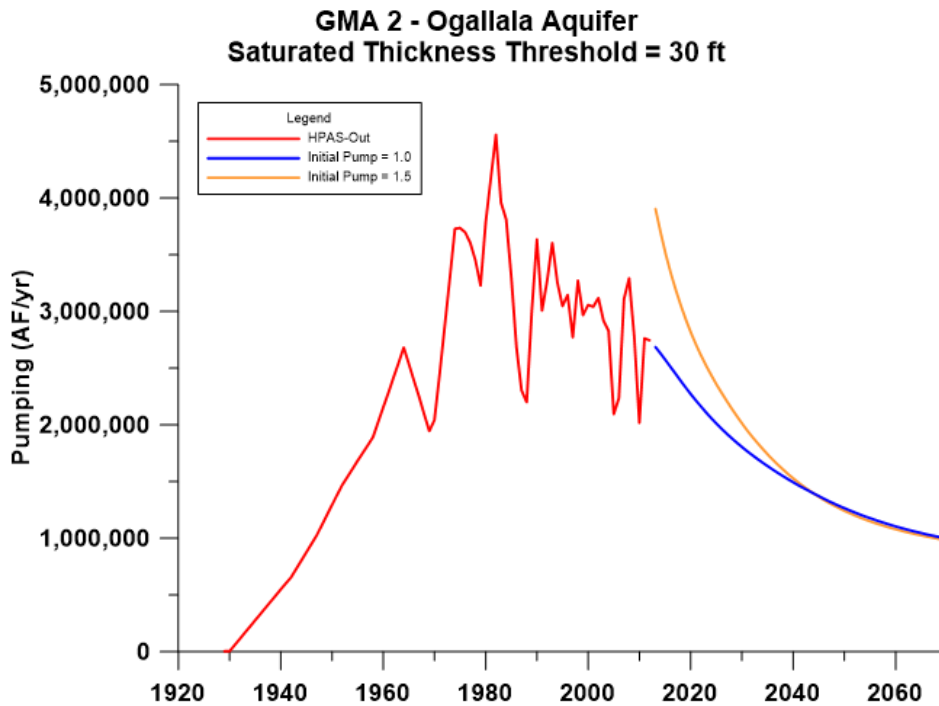

Figure 4. Historic and Simulated Future Pumping – Ogallala and Edwards-Trinity (High Plains) Aquifers in GMA 2

Figure 5. Simulated Average Drawdown – Ogallala and Edwards-Trinity (High Plains) Aquifers in GMA 2

2.3.2 Dockum Aquifer

On October 19, 2016, the groundwater conservation districts in Groundwater Management Area 2 adopted the desired future condition for the Dockum Aquifer. The desired future condition for the Dockum Aquifer was expressed as an average drawdown of 27 feet for all of GMA 2. The drawdown is calculated from the end of 2012 conditions to the year 2070 and was based on Scenario 16 as documented in GMA 2 Technical Memorandum 16-01.

The average drawdown was calculated over the entire extent of the modeled area (not just the official aquifer boundary as defined by TWDB). Much of the area of the Dockum Aquifer in GMA 2 is brackish groundwater with salinity of over 3,000 mg/l total dissolved solids. Typically, TWDB does not recognize these areas as part of the official aquifer boundary. However, the groundwater conservation districts in GMA 2 have included these areas and expect that this resource will be developed in the future.

Historic and simulated future pumping from the Dockum Aquifer is presented in Figure 6, and the simulated drawdown associated with the simulated future pumping is presented in Figure 7.

**Explanatory Report for Desired Future Conditions *(Final)*
Ogallala, Edwards-Trinity (High Plains), and Dockum Aquifers for Groundwater Management Area 2**

Figure 6. Historic and Simulated Future Pumping - Dockum Aquifer in GMA 2

Figure 7. Simulated Average Drawdown - Dockum Aquifer in GMA 2

2.4 2021 Desired Future Conditions

One of the uses of the modeled available groundwater (MAG) is to provide groundwater availability numbers to the Regional Water Planning groups. TWDB has advised all Groundwater Management Areas in Texas that, for this round of joint planning, TWDB will calculate MAGs through the year 2080. Because the primary characteristic of groundwater management in Groundwater Management Area 2 is the reduced groundwater production rates associated with

**Explanatory Report for Desired Future Conditions *(Final)*
Ogallala, Edwards-Trinity (High Plains), and Dockum Aquifers for Groundwater Management Area 2**

declining saturated thickness of the Ogallala Aquifer, it was necessary for GMA 2 to complete an updated simulation with the Groundwater Availability Model to extend the simulation period an additional 10 years.

The groundwater conservation districts in Groundwater Management Area 2 met on May 19, 2020 to discuss any needed updates to the desired future conditions. The joint planning process included a review of the November 1, 2016 Explanatory Report and the associated Technical Memoranda associated with the desired future condition adopted on October 19, 2016. The discussion during the May 19, 2020 meeting also included reviewing the results of an updated simulation with the Groundwater Availability Model that extended the simulation to 2080. After discussion, it was agreed that the underlying basis for the desired future conditions adopted on October 16, 2016, and the previous review of the nine statutory factors were sound. It was agreed that no modification was needed. However, there was a request to modify the simulation with respect to the simulated pumping in the Dockum Aquifer in selected counties.

As documented in GMA 2 Technical Memorandum 20-01, the base simulation that extended the 2016 simulation to 2080 was expanded to simulate alternative additional pumping in the Dockum Aquifer in Dawson, Gaines, Howard, and Martin counties. These simulations were reviewed at a GMA 2 meeting held on January 25, 2021, and Scenario 19 from GMA 2 Technical Memorandum 20-01 was chosen to be the basis of the 2021 desired future condition.

On March 25, 2021, the groundwater conservation districts in Groundwater Management Area 2 voted to propose desired future conditions as follows:

- A GMA 2-wide average drawdown of 28 feet between 2013 and 2080 for the Ogallala and Edwards-Trinity (High Plains) aquifers
- A GMA 2-wide average drawdown of 31 feet between 2013 and 2080 for the Dockum Aquifer

As documented in GMA 2 Technical Memorandum 20-01, the average drawdown calculations involve summing the drawdowns in all cells in an identified unit (e.g. county or GCD) and dividing the sum by the number of cells in the unit. Calculated average drawdowns based on the active cells in the model can be different than the calculated average drawdown based on the official aquifer boundary cells, which are often limited to groundwater less than 3,000 mg/l total dissolved solids. Because the GCDs in GMA 2 are actively managing groundwater with total dissolved solids greater than 3,000 mg/l, GMA 2 decided to express the average drawdown desired future conditions based on the active model cell average, not the official aquifer boundary average. Thus, modeled available groundwater values should also include active model area pumping totals, not the official aquifer boundary totals.

On August 17, 2021, after discussion of the comments received during the public comment period, the groundwater conservation districts in Groundwater Management Area 2 voted to adopt the proposed desired future conditions without modification. The resolutions and notices for this meeting are included as Appendix A.

3.0 Policy Justification

As developed more fully in this report, the desired future condition was adopted after considering:

- Aquifer uses and conditions within Groundwater Management Area 2
- Water supply needs and water management strategies included in the 2012 State Water Plan
- Hydrologic conditions within Groundwater Management Area 2 including total estimated recoverable storage, average annual recharge, inflows, and discharge
- Other environmental impacts, including spring flow and other interactions between groundwater and surface water
- The impact on subsidence
- Socioeconomic impacts reasonably expected to occur
- The impact on the interests and rights in private property, including ownership and the rights of landowners and their lessees and assigns in Groundwater Management Area 2 in groundwater as recognized under Texas Water Code Section 36.002
- The feasibility of achieving the desired future condition
- Other information

In addition, the desired future condition provides a balance between the highest practicable level of groundwater production and the conservation, preservation, protection, recharging, and prevention of water of groundwater in Groundwater Management Area 2.

As discussed earlier, the DFC that was adopted for the High Plains UWCD area of GMA 2 for the Ogallala Aquifer in 2010 was based on a concept where equality in outcome was emphasized more than a management approach that considered the hydraulic characteristics of the aquifer, the hydraulics of pumping wells in an unconfined aquifer where groundwater levels are dropping, and the associated economics of pumping groundwater for irrigation in an area where groundwater levels are dropping. The DFC that is described in this explanatory report puts more emphasis on aquifer hydraulics, economics, and property rights than were considered before, at least in High Plains UWCD area of GMA 2 for the Ogallala Aquifer.

4.0 Technical Justification

The desired future conditions were developed based, in part, on simulations of alternative scenarios of future pumping using the Groundwater Availability Model (GAM) of the Ogallala, Edwards-Trinity (High Plains) and Dockum aquifers (Deeds and Jigmond, 2015). This model utilizes a finite-difference code by the US Geological Survey that dynamically simulates the effect of declining groundwater levels on well production rates. Consequently, this model was used to evaluate the expected pumping rate declines in GMA 2 in the future under a wide variety of alternatives.

4.1 Model Simulations in 2015 and 2016

In 2015, GMA 2 completed 15 alternative simulations to understand the relationship between declining groundwater levels and reduced pumping rates. This analysis was documented in three technical memoranda (Hutchison, 2015a, 2015b, and 2015c). Based on the review of the results of Scenario 1 to 15, GMA 2 directed that a final simulation be completed (Scenario 16) as follows:

- GMA 2 requested that initial (beginning of 2013) Ogallala pumping be set to 150 percent of 2012 pumping and set the saturated thickness threshold to 30 feet to be consistent with the value used during the calibration period of the model. This essentially corresponds to the approach taken in Scenario 10 in GMA 2 Technical Memorandum 15-01. GMA 2 representatives also asked that results from the Ogallala and Edwards-Trinity (High Plains) aquifers be combined. This corresponds to layers 1 and 2 of the GAM in GMA 2. The DFC that was adopted for GMA 2 in 2010 combines the two aquifers, and the aquifers are managed as a single unit.
- Initial (2013) pumping for the Edwards-Trinity (High Plains) was set to either 150 percent of 2012 pumping or on the historic maximum depending on county. Scenario 10 used a consistent 150 percent of 2012 pumping, but historic pumping was higher in earlier years. GMA 2 representatives requested that pumping in those counties correspond to the historic maximum.
- Pumping in the Dockum Aquifer was also set to either 150 percent of 2012 pumping or historic maximum. In addition, areas with no historic pumping were assigned pumping. These counties typically fall outside the official TWDB boundaries of the Dockum Aquifer but were included in the model.

The results for Scenario 16 are documented in GMA 2 Technical Memorandum 16-01 (Hutchison, 2016). In reality, pumping withdrawals will vary according to rainfall. This is observed in the model calibration plots, where cyclical patterns of withdrawal are evident. The range of expected pumping in the development of the desired future condition accounts for uncertainty and timing of drought periods.

4.2 Model Limitations in Howard County

As discussed in the documentation for Scenario 16 (GMA 2 Technical Memorandum 16-01), development of DFCs on a county scale based on the GAM is inappropriate based on a review of the results for several counties. The GAM provides reasonable results on a regional scale (i.e. GMA 2). Thus, the limitations of the GAM were used and acknowledged in the development of these proposed DFCs.

Of note was the discussion of issues in Howard County. Recharge was conceptualized for the entire region and was not adjusted during model calibration on a smaller scale to address clear weaknesses. This approach resulted in an estimated Ogallala Aquifer recharge in Howard County prior to 1959 of about 3,000 AF/yr. Starting in 1959, recharge in Howard County was increased

Explanatory Report for Desired Future Conditions *(Final)*
Ogallala, Edwards-Trinity (High Plains), and Dockum Aquifers for Groundwater Management Area 2

each year until it reached its “modern” value of about 23,000 AF/yr in 1982. Dockum Aquifer recharge from 1930 to 1956 was about 3,000 AF/yr in Howard County. Dockum Aquifer recharge in Howard County increased each year until 1979, when it reached its “modern” value of about 5,200 AF/yr.

The use of this conceptual approach affects the results of the model when it is used as a predictive tool in Howard County, even when the simulation is run to the year 2070. Essentially, the transient effect of the increased recharge persists for decades. Similar problems exist in other counties to varying degrees, especially in the Dockum Aquifer, and Howard County is presented for illustrative purposes.

The significance of the persistence of the effect of the increased recharge is manifested in the storage change hydrograph for the Ogallala and Edwards-Trinity (High Plains) aquifers presented and discussed in GMA Technical Memorandum 16-01 (Hutchison, 2016), and is reproduced here as Figure 8.

Figure 8. Howard County Storage Change from HPAS – Ogallala and ETPH Aquifer

Note that prior to the increase in recharge (1959) storage was declining. When recharge was increased after 1959, storage was increasing. The simulated increase in pumping in 2013 associated with Scenario 16 resulted in a rapid decline in storage, but by about 2050, storage was once again stable and shows a slight gain each year. This analysis is useful to understand why the

**Explanatory Report for Desired Future Conditions *(Final)*
Ogallala, Edwards-Trinity (High Plains), and Dockum Aquifers for Groundwater Management Area 2**

average drawdown in Howard County in the Ogallala Aquifer in Scenario 16 is essentially zero. It also shows that use of the average drawdown from any model run of the HPAS would be an inappropriate basis for a desired future condition in Howard County.

4.3 Model Simulations in 2020

In 2020, the model files associated with Scenario 16 were extended for 10 years to complete a simulation through 2080 to provide a basis for TWDB to calculate modeled available groundwater values for 2080 in support of the regional water planning process. This simulation was designated Scenario 16 – extended to 2080.

GMA 2 also completed Scenarios 17 to 21 to evaluate alternatives of increasing simulated Dockum Aquifer pumping from 2014 to 2018 in Dawson, Gaines, Howard, and Martin counties. After review and discussion at the January 25, 2021 GMA 2 meeting, Scenario 19 from GMA 2 Technical Memorandum 20-01 was chosen to be the basis of the 2021 desired future condition.

5.0 Factor Consideration

Section 36.108(d) of the Texas Water Code requires that groundwater conservation districts include documentation of how nine listed factors were considered prior to proposing a desired future condition, and how the proposed desired future condition impact each factor. This section of the explanatory report summarizes the information that the groundwater conservation districts used in its deliberations and discussions.

5.1 Aquifer Uses and Conditions

For the purposes of the development of a desired future condition, the groundwater conservation districts in Groundwater Management Area 2 considered the following in the category of aquifer uses (i.e. pumping):

- Estimates of 1930 to 2012 input and output pumping from the GAM (Deeds and Jigmond, 2015)
- Estimates of pumping from 1980 and 1984 to 2013 from the TWDB groundwater pumping database
- Current modeled available groundwater for 2010 to 2060
- Estimates of pumping from the initial predictive simulation that was completed for GMA 1 as part of the contract to develop the GAM for 2013 to 2070

These estimates were summarized, presented and discussed at the April 29, 2015 meeting of GMA 2. The estimates associated with the GAM (historic and future) were based on the preliminary model, and much of the discussion was preparing comments for the draft model.

The discussion of these estimates also included comparing the historic pumping to the current modeled available groundwater, and how the new GAM was capable of better simulating the

**Explanatory Report for Desired Future Conditions (*Final*)
Ogallala, Edwards-Trinity (High Plains), and Dockum Aquifers for Groundwater Management Area 2**

expected continued declines in pumping rates associated with declining groundwater levels in the Ogallala Aquifer. Finally, the discussion reviewed the inherent problems of establishing a 50/50 DFC given the historic aquifer uses, expected future uses, and aquifer conditions across GMA 2.

The presentation that was used during the April 29, 2015 meeting is included in this explanatory report as Appendix B.

5.2 Water Supply Needs and Water Management Strategies

The 2016 Region O Plan lists recommended water management strategies, some of which are for local groundwater development. The underlying basis for the proposed DFC is that pumping in the Ogallala Aquifer would increase to 150 percent of estimated 2012 pumping in 2013. The elevated level of 2012 pumping represents a scenario of increased usage during drought conditions. Future reductions in pumping through 2070 would be as a result of declining groundwater levels and the associated change in the hydraulics of pumping wells.

The recommended strategies are generally relatively small amounts of increased groundwater pumping in the Ogallala of up to about 2,600 AF/yr (most are a few hundred acre-feet per year). The Ogallala DFC is consistent with these strategies.

The recommended strategies also include the development of brackish groundwater. The Dockum DFC explicitly included increased pumping for the Dockum to accommodate these strategies, including areas of the Dockum that are not currently within the official boundaries of the Dockum Aquifer (as defined by TWDB) due to poor water quality.

5.3 Hydrologic Conditions within Groundwater Management Area 2

As required by statute, the groundwater conservation districts in Groundwater Management Area 2 considered total estimated recoverable storage, average annual recharge, inflows, and discharge prior to adopting a proposed desired future condition.

5.3.1 Total Estimated Recoverable Storage (TERS)

As required by statute, the Texas Water Development Board provided the groundwater conservation districts in Groundwater Management Area 2 with estimates of total recoverable storage (Kohlrenken and others, 2013). The report is included as Appendix C.

The TWDB storage estimates were developed based on the hydrogeologic framework and aquifer parameters of the old GAMs. The release of the new GAM (Deeds and Jigmond, 2015) postdated the report, and the TERS estimates have not been updated using the new GAM as of mid-2021. In working with storage volumes in the simulation results, the new GAM was used.

It is also noteworthy that the TERS estimates were taken from the last year of model calibration. For the Ogallala and Edwards-Trinity (High Plains), the TERS calculation was year 2000. The Dockum TERS estimates are based on 1997 data.

**Explanatory Report for Desired Future Conditions *(Final)*
Ogallala, Edwards-Trinity (High Plains), and Dockum Aquifers for Groundwater Management Area 2**

5.3.2 *Average Annual Recharge, Inflows and Discharge*

The average groundwater budget for Groundwater Management Area 2 for the Ogallala and Edwards-Trinity (High Plains) aquifers based on the calibrated GAM (Deeds and Jigmond, 2015) for the historic period 1930 to 2012 alongside the groundwater budget for the proposed DFC from 2013 to 2070 is summarized in Table 1.

The average groundwater budget for Groundwater Management Area 2 for the Dockum Aquifer based on the calibrated GAM (Deeds and Jigmond, 2015) for the historic period 1930 to 2012 alongside the groundwater budget for the proposed DFC from 2013 to 2070 is summarized in Table 2.

Time-series plots of each component of the water budget for all years are presented in Hutchison (2016), the documentation for Scenario 16 upon which the DFCs are based. These graphs provide context to the changes in each component over time and because of changes to pumping.

| Model Error | -1 | -3 |

5.4 Other Environmental Impacts, Including Spring Flow and Other Interactions between Groundwater and Surface Water

The evaluation of all water budget components was discussed in Section 5.3.2 above.

5.5 Subsidence

Subsidence has not been an issue historically in these aquifers in GMA 2.

Applying the desired future condition average drawdown to the recently released subsidence tool on the Texas Water Development Board website, the Total Weighted Risk for the Ogallala Aquifer is 5.00 and is 3.59 for the Dockum Aquifer. As noted in the tool, a risk score of 0 is low risk and a risk score of 10 is high risk. Predicted subsidence using the tool is 0.00 feet for the Dockum Aquifer and 0.08 feet for the Ogallala Aquifer from 2010 to 2080.

5.6 Socioeconomic Impacts

Texas Tech and Texas AgriLife Extension Services published a report in 2011 that assessed the economics of proposed groundwater management strategies in Groundwater Management Area 2 (Weinheimer and others, 2011). This report stated that the declining saturated thickness would result in 33 percent fewer irrigated acres over the next 50 years as the region converts to dryland production. The study also found that the aggregate economic impacts from the selected water management policies implemented by the districts will have “very little negative impact relative to the baseline scenario”.

Please note that this conclusion was based on the 2010 DFC, which included a 50/50 concept for the High Plains UWCD area of GMA 2. It was noted in the report that it was possible that individual farms could be impacted by the “proposed strategies”, especially those with very high wells yields and the ability to apply irrigation water over a long period of time.

The areas that would be impacted include those where pumping is artificially and arbitrarily limited to achieve an equal 50/50 condition across the entire area. The concept of equal outcomes was specifically rejected as part of the development of the proposed DFC for the Ogallala discussed in this explanatory report. The DFCs adopted in 2016 and 2021 implicitly recognize the variability of the aquifer (e.g. saturated thickness and well yields) and recognize that differences in pumping in various areas of GMA 2 are, in part, the result of the economics of pumping groundwater for beneficial use.

Thus, the limited economic impacts of the DFCs adopted in 2010 found in Weinheimer and others (2011) are substantially eliminated by the DFCs adopted in 2016 and 2021.

5.7 Impact on Private Property Rights

The impact on the interests and rights in private property, including ownership and the rights of landowners and their lessees and assigns in Groundwater Management Area 2 in groundwater are recognized under Texas Water Code Section 36.002.

The DFC is consistent with protecting property rights. As discussed in the socioeconomic impacts discussion in Section 5.6, under the 50/50 concept, Weinheimer and others (2015) found a limited condition where there could be impacts as the result of the imposition of an equal outcome management concept that is embedded in the 2010 DFCs. The 2016 and 2021 DFCs have eliminated that concern since the current DFCs implicitly recognizes that the aquifer conditions vary across the region, and that property rights are best protected when the pumping is limited only by the physics of groundwater flow and by the economics of pumping groundwater for a beneficial use.

5.8 Feasibility of Achieving the Desired Future Condition

Groundwater levels are routinely monitored by the districts and by the TWDB in GMA 2. Evaluating the monitoring data is a routine task for the districts, and the comparison of these data with the model results that were used to develop the DFCs is covered in each district's management plan. These comparisons will be useful to guide the update of the DFCs that are required every five years.

5.9 Other Information

GMA 2 did not consider any other information in developing the DFCs.

6.0 Discussion of Other Desired Future Conditions Considered

During the development of the proposed DFCs in 2016, a total of sixteen GAM simulations were evaluated and considered. As described earlier, the initial fifteen simulations were used to develop Scenario 16, which was the basis for the proposed DFC.

Also considered in 2015 and 2016 was continuation of a 50/50 concept. However, as described in more detail above, this equal-outcome approach was rejected in favor of proposed DFCs that implicitly considered aquifer conditions and aquifer variability, economics of pumping groundwater in light of declining groundwater levels, and property rights over an arbitrary approach that emphasizes equal outcomes on a county scale.

In 2020, five additional GAM simulations were evaluated relative to alternative Dockum Aquifer pumping scenarios. The results of the additional simulations were reviewed and discussed in early 2021, and selected Scenario 19 as the basis for the proposed DFC as documented in Technical Memorandum 20-01..

7.0 Discussion of Other Recommendations

Public comments were invited, and each district held a public hearing on the proposed desired future condition as follows:

| Groundwater Conservation District | Date of Public Hearing | Number of Comments Received |
|-----------------------------------|--|-------------------------------|
| Garza County UWCD | April 29, 2021 | None |
| High Plains Water District | June 8, 2021 (Lubbock) and July 13, 2021 (Canyon) | 1 written, 2 oral comments |
| Llano Estacado UWCD | June 17, 2021 | None |
| Mesa UWCD | June 16, 2021 | None |
| Permian Basin UWCD | June 15, 2021 | None |
| Sandy Land UWCD | June 16, 2021 | None |
| South Plains UWCD | June 15, 2021 | None |

7.1 Oral Comments at Public Hearings

Two persons offered comments at the July 13 2021 HPWD public hearing.

- 1) Jim Steiert of Hereford told the Board that setting a Desired Future Condition is a difficult and elusive topic. He is impressed by those in Hemphill County who have worked to set a DFC that allows for preservation of springs. Steiert said he believes it is a fallacy for water planners to say we will have a percentage of water left 50 years in the future. People are running out of water now. We have attempted to manage the resource all these years--but have we really been successful? He encouraged the GCDs to work harder to preserve and recharge the water we currently have available--so that it will be available in 50 years. This includes taking care of playas for improved recharge to aquifers, promoting rainwater harvesting, and educating the public.

- 2) Chris Grotegut of Hereford told the Board that he understands the legal ramifications of GCDs not setting a DFC within their respective GMA. Setting a DFC is a difficult target for GCDs. It is a fact that some areas will have water in the future while other areas will not. However, Grotegut said it is important to realize that "zero = zero." No water equals no life in those areas. If some of the area is converted to grasslands, then some portions will recover quickly, and others will not. In his opinion, it is important to balance water usage with recharge to the aquifer. This is probably not possible--but he wonders how low people are willing to drop the water table level.

Mr. Steiert's comment that it is a "fallacy" to express groundwater availability as "a certain percentage of water left 50 years in the future" is fully discussed in this explanatory report. As developed in more detail in Sections 2.2, 2.3, and 2.4, the groundwater conservation districts in Groundwater Management Area 2 specifically rejected the 50/50 concept that had been used in 2010. The desired future conditions adopted in 2016 and 2021 do not employ this approach. Mr.

**Explanatory Report for Desired Future Conditions *(Final)*
Ogallala, Edwards-Trinity (High Plains), and Dockum Aquifers for Groundwater Management Area 2**

Steiert's comment regarding encouraging GCDs to preserve and recharge the "water we currently have available" is the focus of the mission of GCDs. Documentation of all the aspects of how GCDs meet these responsibilities can be found in the management plans of each district in GMA 2.

Mr. Grotegut's comment on the need to balance "water usage with recharge to the aquifer" is one of the primary responsibilities of the groundwater conservation districts in the joint planning process and is documented in this explanatory report. Mr. Grotegut's comment on how low water table levels will drop is also covered in this explanatory report and the associated technical memoranda.

7.2 Written Comments

An undated letter signed by "A Concerned Citizen" was received by High Plains Water District on June 23, 2021 (with a postmark of June 21, 2021). The letter writer recited some general facts regarding the rapid rate of historical groundwater level decline and associated decline in well production rates. The letter writer also acknowledges that there is a fine line between regulation and "property rights/profitability for our farmers". The letter writer proposes:

- Prohibition of pumping irrigation wells which do not have at least 30 feet of saturated thickness
- Ban pumping an irrigation well which cannot produce 50+ gallons per minute

These comments involve specific regulatory recommendations that are beyond the scope of the joint planning process and beyond the charge of GMA 2. These would be issues handled by a GCD, in this case High Plains Water District. However, the information and analyses in this explanatory report and the associated technical memoranda provide a foundation to understand the big picture aspects of these concerns (i.e. reduction of pumping capacity associated with decreasing saturated thickness) in terms of the past, present, and future.

Appendix A
Desired Future Conditions Resolution

Groundwater Management Area 2 Resolution 21-01

Desired Future Conditions for the Ogallala, Edwards-Trinity (High Plains), and Dockum Aquifers in Groundwater Management Area 2

WHEREAS, Groundwater Conservation Districts (GCDs) located within or partially within Groundwater Management Area 2 (GMA 2) are required under Chapter 36.108, Texas Water Code to conduct joint planning and designate the Desired Future Conditions of aquifers within GMA 2 and;

WHEREAS, the Board Presidents or their Designated Representatives of GCDs in GMA 2 have met in various meetings and conducted joint planning in accordance with §36.108, Texas Water Code since September 2010; and

WHEREAS, the GMA 2 committee has received and considered Groundwater Availability Model runs and other technical advice regarding local aquifers, hydrology, geology, recharge characteristics, the nine factors set forth in §36.108(d) of the Texas Water Code, local groundwater demands and usage, population projections, total water supply and quality of water supply available from all aquifers within the respective GCDs, regional water plan water management strategies, ground and surface water interactions, that affect groundwater conditions through the year 2070; and

WHEREAS, the member GCDs of GMA 2, having given proper and timely notice, held an open meeting on March 25, 2021 at a remote meeting via Zoom, to vote to adopt proposed Desired Future Conditions for the Ogallala, Edwards-Trinity (High Plains), and Dockum aquifers within the boundaries of GMA 2; and

WHEREAS, the member GCDs in which the Ogallala, Edwards-Trinity (High Plains), and Dockum aquifers are relevant for joint planning purposes held open meetings within each said district between April 29, 2021 and July 13, 2021 to take public comment on the proposed DFCs for that district; and

WHEREAS on this day of August 17, 2021, at an open meeting duly noticed and held in accordance with law at the offices of High Plains Water District located at 2930 Avenue Q, Lubbock, Texas, 79411, having considered at this meeting comments submitted to the individual districts during the comment period and at this meeting, have voted, **6 districts in favor, 1 district absent**, to adopt the following DFCs for in the following counties and districts through the year 2080 as follows:

- A GMA 2-wide average drawdown of 28 feet between 2013 and 2080 for the Ogallala and Edwards-Trinity (High Plains) aquifers
- A GMA 2-wide average drawdown of 31 feet between 2013 and 2080 for the Dockum Aquifer

NOW THEREFORE BE IT RESOLVED, that Groundwater Management Area 2 does hereby document, record, and confirm the above-described Desired Future Conditions for the Ogallala, Edwards-Trinity (High Plains), and Dockum Aquifer which were adopted by vote of the following Designated Representatives of Groundwater Conservation Districts present and voting on August 17, 2021:

for Garza County UWCD

for High Plains UWCD #1

for Llano Estacado UWCD

for Mesa UWCD

for Permian Basin UWCD

for Sandy Land UWCD

for South Plains UWCD

Groundwater Management Area 2 Resolution 21-02

Declaration that the Edwards-Trinity (Plateau) and Pecos Valley Aquifers Are Not Relevant for Purposes of Joint Planning in Groundwater Management Area 2

WHEREAS, Groundwater Conservation Districts (GCDs) located within or partially within Groundwater Management Area 2 (GMA 2) are required under Chapter 36.108, Texas Water Code to conduct joint planning and designate the Desired Future Conditions of aquifers within GMA 2 and;

WHEREAS, the Board Presidents or their Designated Representatives of GCDs in GMA 2 have met in various meetings and conducted joint planning in accordance with §36.108, Texas Water Code since September 2010; and

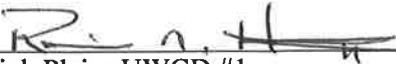

WHEREAS, the GMA 2 committee has received and considered Groundwater Availability Model runs and other technical advice regarding local aquifers, hydrology, geology, recharge characteristics, the nine factors set forth in §36.108(d) of the Texas Water Code, local groundwater demands and usage, population projections, total water supply and quality of water supply available from all aquifers within the respective GCDs, regional water plan water management strategies, ground and surface water interactions, that affect groundwater conditions through the year 2070; and

WHEREAS on this day of August 17, 2021, at an open meeting duly noticed and held in accordance with law at the offices of High Plains Water District located at 2930 Avenue Q, Lubbock, Texas, 79411 the GCDs within GMA 2, and voted to adopt proposed Desired Future Conditions for the aquifers of the GMA; and

WHEREAS at said meeting held on August 17, 2021, the GCDs within GMA2 voted, upon motion made and seconded, **6 districts in favor, 1 district absent**, to declare the Edwards-Trinity (Plateau) and Pecos Valley aquifers not relevant for purposes of joint planning pursuant to Section 36.108 of the Texas Water Code and therefore not requiring the establishment of DFCs by GMA 2, nor the determination by the Texas Water Development Board (TWDB) of Modeled Available Groundwater (MAGs) for those aquifers in GMA 2,

NOW THEREFORE BE IT RESOLVED, that Groundwater Management Area 2 does hereby document, record, and confirm the above declaration that the Edwards-Trinity (Plateau) and Pecos Valley aquifers are not relevant for purposes of joint planning and therefore not requiring the establishment of DFCs by GMA 2, nor the determination by the Texas Water Development Board (TWDB) of Modeled Available Groundwater (MAGs) for those aquifers in GMA 2, approved by the following votes of the designated representatives of Groundwater Conservation Districts in GMA 2:

for Garza County UWCD

for High Plains UWCD #1

for Llano Estacado UWCD

for Mesa UWCD

for Permian Basin UWCD

for Sandy Land UWCD

for South Plains UWCD

COUNTY CLERK, LUBBOCK COUNTY, TEXAS

Joint Planning For Groundwater Management Area # 2

Tuesday, August 17, 2021

10:00 AM

HPWD Office, 2930 Avenue Q, Lubbock, TX 79411-2499

As required by Chapter 36.108(e) Texas Water Code, notice is hereby given that the groundwater conservation districts located wholly or partially within Groundwater Management Area # 2 (GMA #2) will participate in a joint planning meeting on the date, time, and location shown above.

At the joint meeting, the presiding officer or their designee as required by Chapter 36.108(c), along with any number of members of the Board of Directors, will convene for the purpose of joint groundwater planning only and not to conduct any other business.

Groundwater Conservation Districts within GMA # 2 are as follows:

Garza County UWCD, High Plains UWCD # 1, Llano Estacado UWCD, Mesa UWCD, Permian Basin UWCD, Sandy Land UWCD, and South Plains UWCD.

The meeting is open to the public and the following items of business will be discussed and potentially acted upon:

AGENDA

1. CALL TO ORDER
2. ROLL CALL AND ESTABLISH QUORUM
3. PUBLIC COMMENT
4. MINUTES
 - March 25, 2021 GMA 2 Meeting Minutes
5. TEXAS WATER DEVELOPMENT BOARD UPDATES
6. AGENDA ITEMS AND UPDATES
 - The GMA # 2 Members Will Discuss Comments On Proposed Desired Future Conditions Received During Public Comment Period And Review Proposed Responses.
 - The GMA # 2 Members Will Consider For Approval A Resolution Regarding Non-Relevant Aquifers For Joint Planning Purposes in GMA # 2.

- The GMA # 2 Members Will Consider For Approval A Resolution For Desired Future Conditions Of Relevant Aquifers In GMA # 2.
- The GMA # 2 Members Will Discuss And Consider For Approval Final Draft Explanatory Report For Adopted Desired Future Conditions.
- The GMA # 2 Members Will Discuss Next Administrative Steps.

7. ITEMS FOR FUTURE AGENDAS

8. ADJOURN

Dated this the 5th day of August, 2021.

By

Jason Coleman, Chair
Groundwater Management Area # 2

Questions regarding this meeting and/or notice should be directed to Jason Coleman, High Plains UWCD # 1, 2930 Avenue Q, Lubbock, TX 79411-2499. (806) 762-0181.
jason.coleman@hpwd.org

I hereby certify that the above Notice of Meeting for Joint Planning for Groundwater Management Area # 2 is a true and correct copy of said Notice. A true and correct copy of said notice was provided at least 10 days prior to the meeting to the Office of the Texas Secretary of State, and to the respective County Clerk of each county located wholly or partly in a district located wholly or partly within the groundwater management area. This notice was also posted at a place readily accessible to the public at the district office of each district located wholly or partially within the management area. This notice was also posted to the GMA # 2 website at www.gma2.org.

Groundwater Use Estimates

Review of Draft High Plains Aquifer System (HPAS) Groundwater Availability Model (GAM)

Bill Hutchison, Ph.D., P.E., P.G.

GMA 2 Meeting

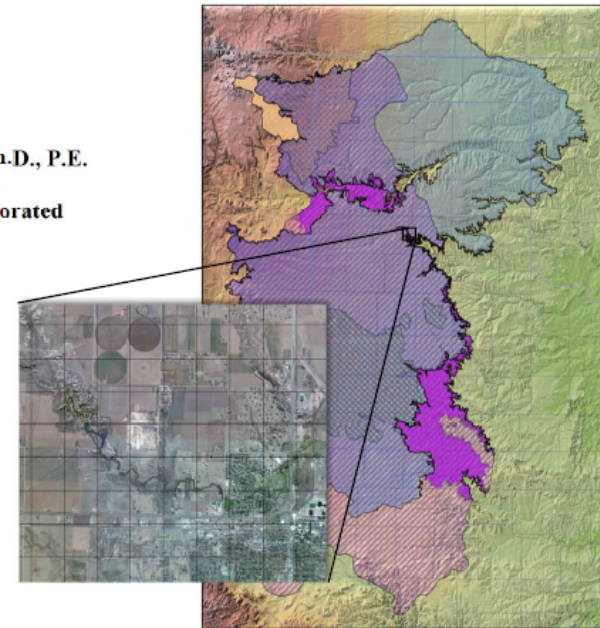

April 29, 2015

Draft Model

- SAF 3 Meeting in Amarillo on February 18, 2015
- Report downloaded April 3, 2015
- Model Files downloaded April 4, 2015
- Deadline to comment is May 6, 2015

Draft Numerical Model Report for the High Plains Aquifer System
Groundwater Availability Model

Prepared by
Neil E. Deeds, Ph.D., P.E.
Marius Jigmond
INTERA Incorporated

Prepared for:
Texas Water Development Board
P.O. Box 13231, Capitol Station
Austin, Texas 78711-3231

March 2015

Topics

- Review draft model in context of DFC development
 - Specific yield
 - Recharge
 - Pumping
- Administrative/Invoicing Discussion
- Next steps for GMA 2

Specific Yield

- Specific yield has a big influence on storage calculations
- At February 18, 2015 SAF meeting, specific yield had not been a calibration parameter
 - “Did not feel it was justified, since no new measurement were available”
- Draft report states that some specific yield values had been modified

Specific Yield in Draft Report

Figure 2.4.6 Specific yield calibration zone.

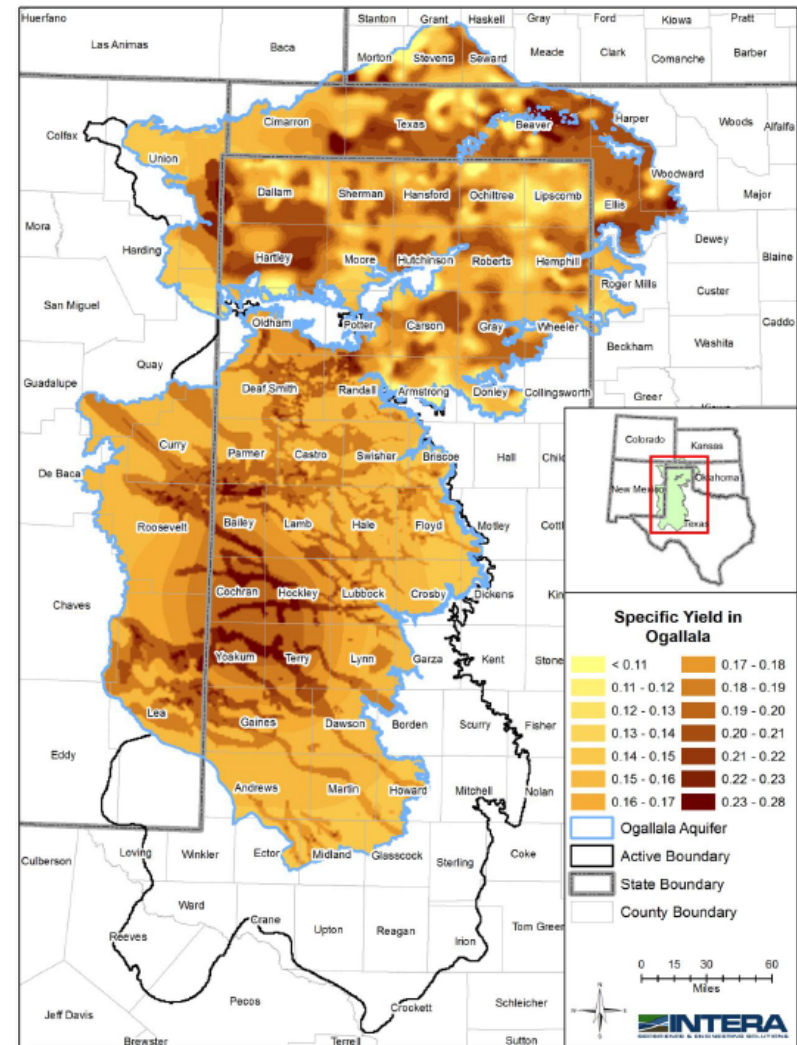

Figure 3.1.9 Calibrated specific yield in the Ogallala Aquifer.

Recharge

- Assumed constant recharge every year (1930 to 2012)
- Recharge includes irrigation return flow in southern portion of model
 - County-by-county “breakthrough” curves (Fig 4.4.15 of Conceptual Model report)

From Conceptual Model Report

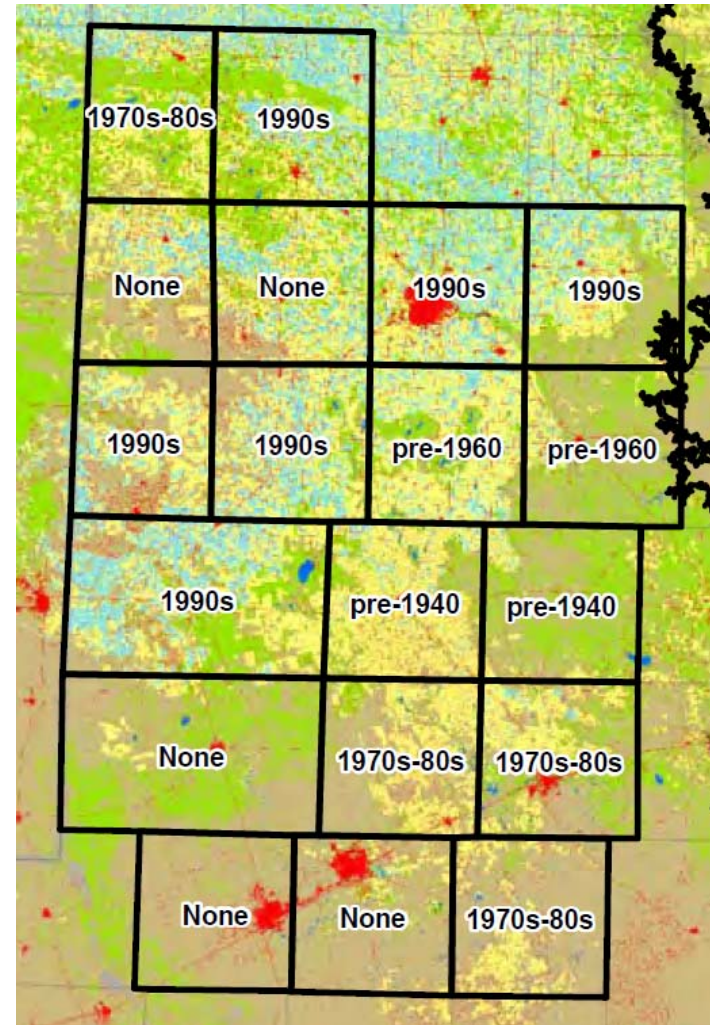

Figure 4.4.15 Timing of recharge compared to land use in southern Ogallala.

Steady State and Transient Recharge

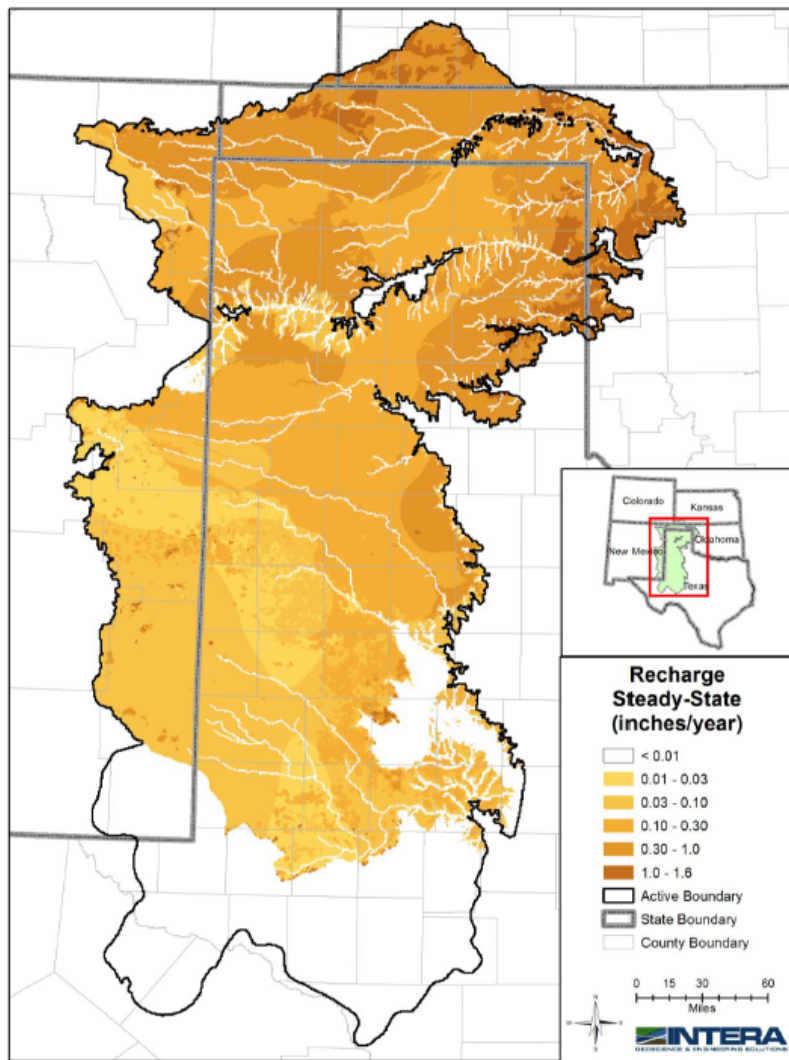

Figure 3.1.13 Calibrated predevelopment (steady-state stress period) recharge distribution.

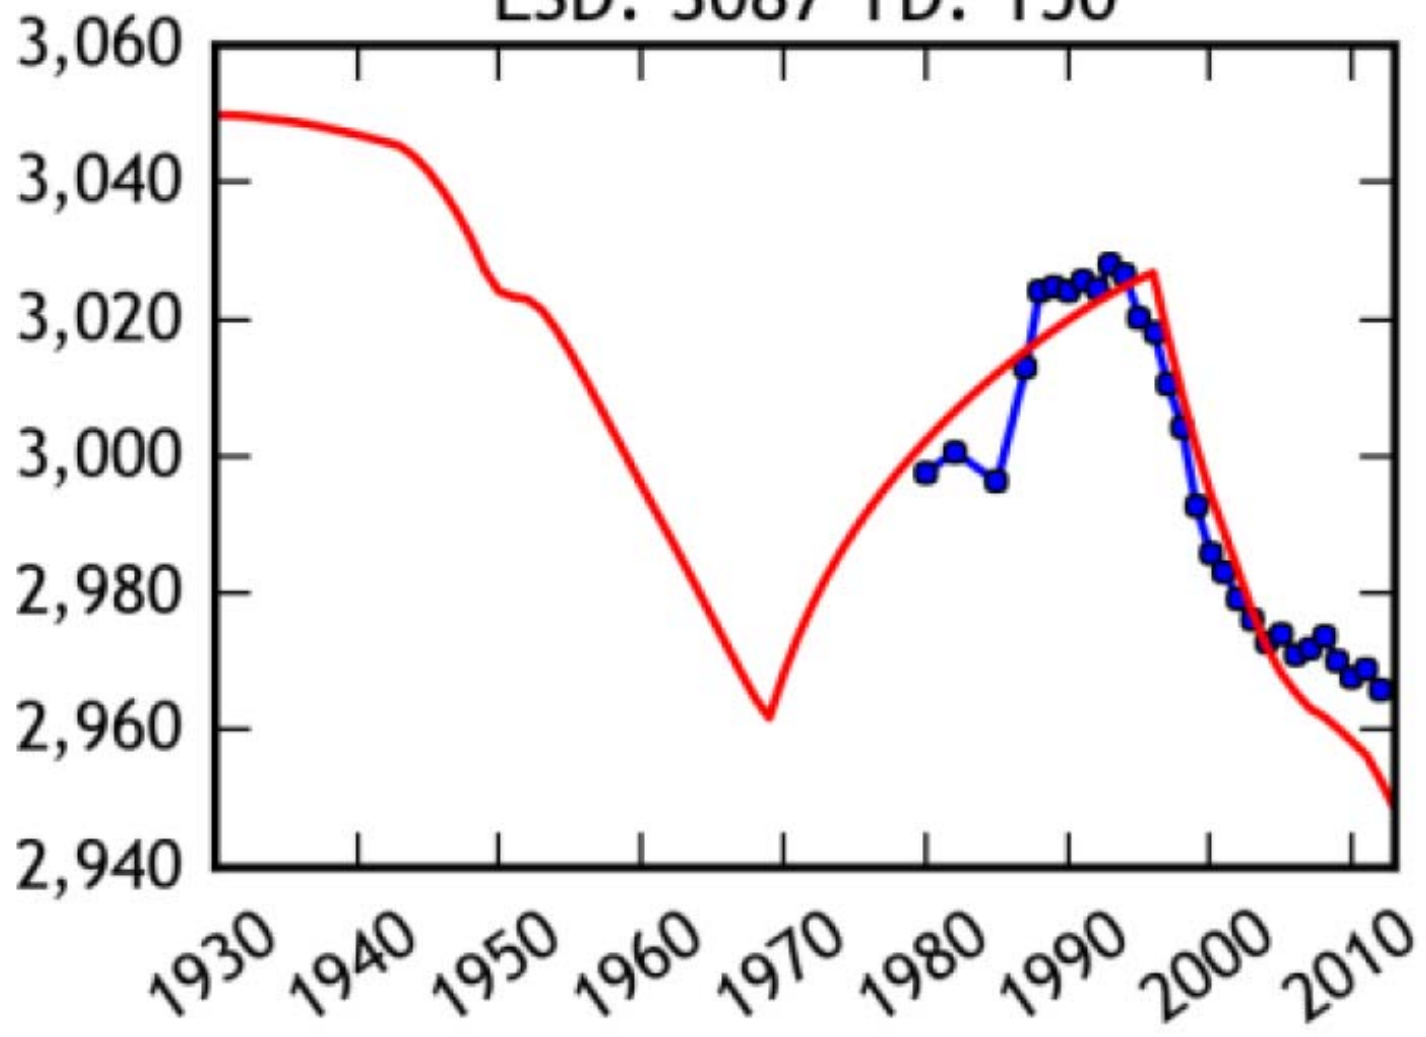

Figure 3.1.14 Calibrated transient recharge distribution in year 2012 (stress period 84).

2708801 (Dawson, TX)
LSD: 3087 TD: 150

2707401 (Gaines, TX)
LSD: 3133 TD: 110

Pumping

- Draft report documents methods to select pumping locations well
- Conceptual model documents pumping amounts
 - Previous model(s)
 - TWDB water use survey data

Initial Intera Simulation for GMA 1

- Received PowerPoint from Jason Coleman on April 24, 2015
- Included summary results for GMA 2
 - Assumed 50/50 for all aquifers (ETHP combined with Ogallala)
 - Summaries of results are presented in context of historic pumping and current MAGs

Summary of Run Requirements

| Region | Aquifer | | | | Reference Start Year | Reference End Year | Simulation End Year | Decline Type |
|-----------------------|-------------------------|---|---------------------------------|----------------------------|----------------------|--------------------|---------------------|--------------|
| | Ogallala | Rita Blanca | ETHP | Dockum | | | | |
| NPGCD: West | 40/50 | Historical Fraction of Dallam Ogallala pumping rate | n/a | 50/50 (available drawdown) | 2016 | 2065 | 2070 | linear |
| NPGCD: East | 2015 Pumping + 100K AFY | n/a | n/a | n/a | 2016 | 2065 | 2070 | linear |
| HCUWCD | 80/50 | n/a | n/a | n/a | 2016 | 2065 | 2070 | linear |
| PGCD | 50/50 | n/a | n/a | 50/50 (available drawdown) | 2016 | 2065 | 2070 | 1.25% |
| HPWD | 50/50 | n/a | Combine thickness with Ogallala | 50/50 (available drawdown) | 2016 | 2065 | 2070 | exponential |
| non-HPWD South | 50/50 | n/a | Combine thickness with Ogallala | 50/50 (available drawdown) | 2016 | 2065 | 2070 | exponential |

Ogallala Aquifer (Layer 1 of HPAS)

- TWDB – groundwater pumping estimates (1980, 1984-2012) from water use surveys
- HPAS
 - Input pumping
 - Output pumping

Note: 2015 rate is based on the historical model (using the rate from 2012), and is provided for comparison to predicted available groundwater. The rate may be a few percent less than was input due to some wells located in areas of small saturated thickness (where rates get scaled back.)

Ogallala Aquifer Summary

- TWDB and HPAS comparison
 - Sometimes agree, sometimes different
 - HPAS estimates are likely more accurate (constrained estimates)
- Intera Scenario 1 pumping
 - Often have large increase in 2020, then sharp decline
 - Sometimes higher than current MAG, sometimes lower

Edwards-Trinity (High Plains) Aquifer (Layer 2 of southern portion of HPAS)

- TWDB – groundwater pumping estimates (1980, 1984-2012) from water use surveys
- HPAS
 - Input pumping
 - Output pumping
- Current MAG
- Did not include Intera results
- Only included counties with TWDB estimates

Note: The very high rates that occur are due to simulated desaturation of the ETHP, when target water levels are below the top of the ETHP. This type of storage change under desaturation of a confined aquifer is not a well-studied phenomenon, and we should treat these results with caution.

ETHP Summary

- HPAS estimates generally consistent with TWDB estimates
- Current MAGs are not consistent with historic pumping (sometimes much higher, sometimes much lower)
 - Old model estimates of historic pumping may not have been based on TWDB historic data?
- Intera scenario combined thickness with Ogallala and sought 50/50
- Need to use historic data as starting point and consider range of increases and decreases

Dockum Aquifer

(Layers 3 and 4 of HPAS)

- TWDB – groundwater pumping estimates (1980, 1984-2012) from water use surveys
- HPAS
 - Input pumping
 - Output pumping
- Current MAG
- Did not include Intera results
- Only included counties with TWDB estimates

Dockum Summary

- HPAS estimates not always consistent with TWDB estimates
- Current MAGs are not consistent with historic pumping (sometimes much higher, sometimes much lower)
 - Old model estimates of historic pumping may not have been based on TWDB historic data?
- Intera scenario sought 50/50 (?)
- Need to use historic data as starting point and consider range of increases and decreases

Administrative/Invoicing Discussion

- Proposal dated September 15, 2014
 - Three phases proposed
 - Firm cost estimate for Phase 1 (complete with comment letter)
 - Range of costs for Phase 2 and 3
 - Discuss initial task of Phase 2
- Confirm contact and email addresses for invoice
- Provide estimate of first invoice to each GCD

Invoice Breakdown

| District | Address | Contact | Email | Allocation (%) | Approximate Invoice |

Activities Completed for GMA 2

- GMA 2 meeting on January 23, 2015
- HPAS SAF meeting on February 18, 2015
 - 1/3 of travel cost and time
- Reviewed model report and files
- Compiled model pumping data and TWDB pumping estimate data
- Reviewed Intera PowerPoint, and integrated it into pumping estimate graphs
- GMA 2 meeting today
 - 1/2 travel cost

Next Steps

- Proposal of September 15, 2014 covered 3 phases:
 - Initial data gathering, DFC strategy, and HPAS review (done as of May 6 with comment letter)
 - Technical assistance in developing Proposed DFC (deadline is May 1, 2016)
 - Technical assistance after Proposed DFC is adopted

Technical Assistance in Developing Proposed DFC

- Initial cost estimate was \$20,000 to \$40,000
 - Attend GMA 2 meetings
 - Completing model runs
 - Complete work associated with nine factors
 - Prepare draft explanatory report

Recommended Initial Model Runs

- Complete initial model runs based on physics of system (reduced pumping based on saturated thickness for Ogallala)
 - Use GMA 1 model files for GMA 1 area
 - Use 2012 rates (Ogallala) and/or historic high rates (other aquifers)
 - Vary initial pumping rates and reduction factor (Ogallala)
 - Increases/decrease initial rates for EHP and Dockum
- Share files with TWDB/Intera by June 1, 2015
- Prepare a technical memorandum by June 26, 2015
- Meeting in July to discuss results and plan next steps
 - Possible SAF meeting in coordination with GMA 2 meeting?
- Cost to complete: not-to-exceed \$9,000

Questions and Discussion

September 19, 2013

Cynthia K. Ridgeway is the Manager of the Groundwater Availability Modeling Section and is responsible for oversight of work performed by William Kohlrenken under her direct supervision. The seals appearing on this document were authorized by Cynthia K. Ridgeway, P.G. 471, Ian C. Jones, P.G. 477, and Radu Boghici, P.G. 482 on September 19, 2013.

The total estimated recoverable storage in this report was calculated as follows: the Dockum Aquifer, Edwards-Trinity (High Plains), and Ogallala aquifers (William Kohlrenken); the Seymour Aquifer (Radu Boghici); and the Edwards-Trinity (Plateau) and Pecos Valley aquifers (Ian Jones).

EXECUTIVE SUMMARY:

Texas Water Code, § 36.108 (d) (Texas Water Code, 2011) states that, before voting on the proposed desired future conditions for a relevant aquifer within a groundwater management area, the groundwater conservation districts shall consider the total estimated recoverable storage as provided by the executive administrator of the Texas Water Development Board (TWDB) along with other factors listed in §36.108 (d). Texas Administrative Code Rule §356.10 (Texas Administrative Code, 2011) defines the total estimated recoverable storage as the estimated amount of groundwater within an aquifer that accounts for recovery scenarios that range between 25 percent and 75 percent of the porosity-adjusted aquifer volume.

This report discusses the methods, assumptions, and results of analyses to estimate the total recoverable storage for the Dockum, Edwards-Trinity (High Plains), Edwards-Trinity (Plateau), Ogallala, Seymour, and Pecos Valley aquifers within Groundwater Management Area 2. Tables 1 through 12 summarize the total estimated recoverable storage required by the statute. Figures 2 through 7 indicate the extent of the groundwater availability models used to estimate the total recoverable storage.

DEFINITION OF TOTAL ESTIMATED RECOVERABLE STORAGE:

The total estimated recoverable storage is defined as the estimated amount of groundwater within an aquifer that accounts for recovery scenarios that range between 25 percent and 75

² This is the office telephone number for William Kohlrenken

percent of the porosity-adjusted aquifer volume. In other words, we assume that between 25 and 75 percent of groundwater held within an aquifer can be removed by pumping.

The total recoverable storage was estimated for the portion of each aquifer within Groundwater Management Area 2 that lies within the official lateral aquifer boundaries as delineated by George and others (2011). Total estimated recoverable storage values may include a mixture of water quality types, including fresh, brackish, and saline groundwater, because the available data and the existing groundwater availability models do not permit the differentiation of different water quality types. These values do not take into account the effects of land surface subsidence, degradation of water quality, or any changes to surface water-groundwater interaction as the result of extracting groundwater from the aquifer.

METHODS:

To estimate the total recoverable storage of an aquifer, we first calculated the total storage in an aquifer within the official aquifer boundary in the groundwater management area. The total storage is the volume of groundwater that can be removed by completely draining the aquifer.

Aquifers can be either unconfined or confined (Figure 1). A well screened in an unconfined aquifer will have a water level equal to the water level in the aquifer outside the well. Thus, unconfined aquifers have water levels within the aquifers. A confined aquifer is bounded by low permeable geologic units at the top and bottom, and the aquifer is under hydraulic pressure above the ambient atmospheric pressure. The water level at a well screened in a confined aquifer will be above the top of the aquifer. As a result, calculation of total storage is also different between unconfined and confined aquifers. For an unconfined aquifer, the total storage is equal to the volume of groundwater that makes the water level fall to the aquifer bottom. For a confined aquifer, the total storage contains two parts. The first part is the groundwater released from the aquifer when the water level falls from above the top of the aquifer to the top of the aquifer. The reduction of hydraulic pressure in the aquifer by pumping causes expansion of groundwater and deformation of aquifer solids. The aquifer is still fully saturated to this point. The second part, just like unconfined aquifer, is the groundwater released from the aquifer when the water level falls from the top to the bottom of the aquifer. Given the same aquifer area and water level drop, the amount of water

released in the second part is much greater than the first part. The difference is quantified by two parameters: storativity related to confined aquifer and specific yield related to unconfined aquifer. For example, storativity values range from 10^{-5} to 10^{-3} for most confined aquifers, while the specific yield values can be 0.01 to 0.3 for most unconfined aquifers. The equations for calculating the total storage are presented below:

- for unconfined aquifers

$$Total\ Storage = V_{drained} = Area \times S_y \times (Water\ Level - Bottom)$$

- for confined aquifers

$$Total\ Storage = V_{confined} + V_{drained}$$

- confined part

$$V_{confined} = Area \times [S \times (Water\ Level - Top)]$$

or

$$V_{confined} = Area \times [S_s \times (Top - Bottom) \times (Water\ Level - Top)]$$

- unconfined part

$$V_{drained} = Area \times [S_y \times (Top - Bottom)]$$

where:

- $V_{drained}$ = storage volume due to water draining from the formation (acre-feet)
- $V_{confined}$ = storage volume due to elastic properties of the aquifer and water(acre-feet)
- $Area$ = area of aquifer (acre)
- $Water\ Level$ = groundwater elevation (feet above mean sea level)
- Top = elevation of aquifer top (feet above mean sea level)
- $Bottom$ = elevation of aquifer bottom (feet above mean sea level)
- S_y = specific yield (no units)
- S_s = specific storage (1/feet)
- S = storativity or storage coefficient (no units)

FIGURE 1. SCHEMATIC GRAPH SHOWING THE DIFFERENCE BETWEEN UNCONFINED AND CONFINED AQUIFERS.

As presented in the equations, calculation of the total storage requires data, such as aquifer top, aquifer bottom, aquifer storage properties, and water level. For the Dockum, Edwards-Trinity (High Plains), Edwards-Trinity (Plateau), Ogallala, and Seymour aquifers in Groundwater Management Area 2, we extracted this information from existing groundwater availability model input and output files on a cell-by-cell basis. This information was contained in model input and output files on a cell-by-cell basis. In the absence of groundwater availability model(s), the total storage will be calculated using other approaches.

Python scripts and a FORTRAN-90 program were developed and used to expedite the storage calculation. The total recoverable storage was calculated as the product of the total storage and an estimated factor ranging from 25 percent to 75 percent.

The following methodology was used to estimate total recoverable storage for parts of the Pecos Valley and Edwards-Trinity (Plateau) aquifers in Groundwater Management Area 2 that were not included in the 1-layered alternative groundwater flow model covering these aquifers (Hutchison and others, 2011). The excluded parts of the respective aquifers are relatively thin, mostly located along the margins of the respective aquifers in the western part of the model.

Recoverable storage in areas outside of the model but within the official aquifer boundaries is estimated by first establishing a relationship between aquifer thickness and saturated thickness. Where aquifer thickness is the difference between the elevations of the aquifer top and base, and saturated thickness is the difference between the water table and aquifer base elevations. In each of the three aquifers included in this model there is a generally linear relationship between aquifer thickness and saturated thickness. In the Pecos Valley Aquifer, the ratio between saturated thickness and aquifer thickness is approximately 0.8, while in the Edwards-Trinity (Plateau) and Trinity aquifers, it is 0.9 and 0.6, respectively. Saturated thickness in the non-modeled areas is estimated using these ratios.

The three aquifers—Pecos Valley and Edwards-Trinity (Plateau) aquifers, and the Hill Country portion of the Trinity Aquifer—are assumed to be unconfined. Consequently, storage in each model cell representing parts of the respective aquifers excluded from the groundwater flow model is estimated using the following equation:

$$Total\ Storage = V_{drained} = Area \times S_y \times H_{sat}$$

where:

- $V_{drained}$ = storage volume due to water draining from the formation (acre-feet)
- $Area$ = area of aquifer (acre)
- S_y = specific yield (no units)
- H_{sat} = estimated saturated thickness (feet)

Storage volumes estimated using this method were added to the storage volumes from the remainder of the modeled area to estimate the total recoverable storage for the entire aquifer.

PARAMETERS AND ASSUMPTIONS:

Dockum Aquifer

- We used version 1.01 of the groundwater availability model for the Dockum Aquifer to estimate the total recoverable storage. See Ewing and others (2008) for assumptions and limitations of the groundwater availability model.
- This groundwater availability model includes three layers which generally represent the younger geologic units overlying the Dockum Aquifer (Layer 1), the upper portion of the Dockum Aquifer (Layer 2), and the lower portion of the Dockum Aquifer (Layer 3).
- Of the three layers, total estimated recoverable storage was determined and combined for layers representing the Dockum Aquifer (layers 2 and 3).
- The down-dip boundary of the Dockum Aquifer in this model was set to approximately coincide with the extent of the available geologic data, well beyond any active portion (groundwater use) of the aquifer (Ewing and others, 2008). Consequently, the model extends into zones of brackish and saline groundwater. The official extent of the Dockum Aquifer was used to exclude this area (George and others, 2011).

Southern portion of the Ogallala Aquifer and Edwards-Trinity (High Plains) Aquifer

- We used version 2.01 of the groundwater availability model to estimate the total recoverable storages of the southern portion of the Ogallala and Edwards-Trinity (High Plains) aquifers. This model is an expansion on and update to the previously developed groundwater availability model for the southern portion of the Ogallala Aquifer described in Blandford and others (2003). See Blandford and others (2008) and Blandford and others (2003) for assumptions and limitations of the groundwater availability model.
- This groundwater availability model includes 4 layers which represent the southern portion of the Ogallala (Layer 1) and the Edwards-Trinity (High Plains) (primarily Edwards, Comanche Peak, and Antlers Sand formations; layers 2-4).

- Of the four layers, total estimated recoverable storage was determined for the Ogallala Aquifer (Layer 1) and Edwards-Trinity (High Plains) Aquifer (layers 2-4) in Groundwater Management Area 2.

Edwards-Trinity (Plateau) and Pecos Valley aquifers

- We used alternative groundwater flow model for the Edwards-Trinity (Plateau) Aquifer. See Hutchison and Others (2011) for assumptions and limitations of the alternative numerical groundwater flow model.
- This 1-layer groundwater flow model simulates groundwater flow through the Pecos Valley and Edwards-Trinity (Plateau) aquifers, and the Hill Country portion of the Trinity Aquifer.
- In this model, where the Pecos Valley and Edwards-Trinity (Plateau) aquifer overlap, total storage is assigned to the Pecos Valley Aquifer.

Seymour Aquifer

- We used version 1.01 of the groundwater availability model for the Seymour and Blaine aquifers. See Ewing and others (2004) for assumptions and limitations of the groundwater availability model.
- This groundwater availability model includes two layers, representing the Seymour (Layer 1) and Blaine (Layer 2) aquifers. In areas where the Blaine Aquifer does not exist the model roughly replicates the various Permian units located in the study area.
- Of the two layers, total estimated recoverable storage was determined using the cells in the model that represent the Seymour Aquifer in Layer 1.

RESULTS:

Tables 1 through 12 summarize the total estimated recoverable storage required by statute. The county and groundwater conservation district total estimates are rounded to two significant figures. Figures 2 through 7 indicate the extent of the groundwater availability models in Groundwater Management Area 2 for the Dockum, Edwards-Trinity (High Plains), Edwards-Trinity (Plateau), Ogallala, Seymour, and Pecos Valley aquifers from which the storage information was extracted.

LIMITATIONS

The groundwater models used in completing this analysis are the best available scientific tools that can be used to meet the stated objective(s). To the extent that this analysis will be used for planning purposes and/or regulatory purposes related to pumping in the past and into the future, it is important to recognize the assumptions and limitations associated with the use of the results. In reviewing the use of models in environmental regulatory decision making, the National Research Council (2007) noted:

“Models will always be constrained by computational limitations, assumptions, and knowledge gaps. They can best be viewed as tools to help inform decisions rather than as machines to generate truth or make decisions. Scientific advances will never make it possible to build a perfect model that accounts for every aspect of reality or to prove that a given model is correct in all respects for a particular regulatory application. These characteristics make evaluation of a regulatory model more complex than solely a comparison of measurement data with model results.”

Because the application of the groundwater model was designed to address regional scale questions, the results are most effective on a regional scale. The TWDB makes no warranties or representations relating to the actual conditions of any aquifer at a particular location or at a particular time.

COUNTY CLERK LUBBOCK COUNTY, TEXAS

Joint Planning For Groundwater Management Area # 2

Tuesday, August 17, 2021

10:00 AM

HPWD Office, 2930 Avenue Q, Lubbock, TX 79411-2499

As required by Chapter 36.108(e) Texas Water Code, notice is hereby given that the groundwater conservation districts located wholly or partially within Groundwater Management Area # 2 (GMA #2) will participate in a joint planning meeting on the date, time, and location shown above.

At the joint meeting, the presiding officer or their designee as required by Chapter 36.108(c), along with any number of members of the Board of Directors, will convene for the purpose of joint groundwater planning only and not to conduct any other business.

Groundwater Conservation Districts within GMA # 2 are as follows:

Garza County UWCD, High Plains UWCD # 1, Llano Estacado UWCD, Mesa UWCD, Permian Basin UWCD, Sandy Land UWCD, and South Plains UWCD.

The meeting is open to the public and the following items of business will be discussed and potentially acted upon:

AGENDA

1. CALL TO ORDER
2. ROLL CALL AND ESTABLISH QUORUM
3. PUBLIC COMMENT
4. MINUTES
 - March 25, 2021 GMA 2 Meeting Minutes
5. TEXAS WATER DEVELOPMENT BOARD UPDATES
6. AGENDA ITEMS AND UPDATES
 - The GMA # 2 Members Will Discuss Comments On Proposed Desired Future Conditions Received During Public Comment Period And Review Proposed Responses.
 - The GMA # 2 Members Will Consider For Approval A Resolution Regarding Non-Relevant Aquifers For Joint Planning Purposes in GMA # 2.

- The GMA # 2 Members Will Consider For Approval A Resolution For Desired Future Conditions Of Relevant Aquifers In GMA # 2.
- The GMA # 2 Members Will Discuss And Consider For Approval Final Draft Explanatory Report For Adopted Desired Future Conditions.
- The GMA # 2 Members Will Discuss Next Administrative Steps.

7. ITEMS FOR FUTURE AGENDAS

8. ADJOURN

Dated this the 5th day of August, 2021.

By

Jason Coleman, Chair
Groundwater Management Area # 2

Questions regarding this meeting and/or notice should be directed to Jason Coleman, High Plains UWCD # 1, 2930 Avenue Q, Lubbock, TX 79411-2499. (806) 762-0181.
jason.coleman@hpwd.org

I hereby certify that the above Notice of Meeting for Joint Planning for Groundwater Management Area # 2 is a true and correct copy of said Notice. A true and correct copy of said notice was provided at least 10 days prior to the meeting to the Office of the Texas Secretary of State, and to the respective County Clerk of each county located wholly or partly in a district located wholly or partly within the groundwater management area. This notice was also posted at a place readily accessible to the public at the district office of each district located wholly or partially within the management area. This notice was also posted to the GMA # 2 website at www.gma2.org.

Groundwater Management Area 2 Resolution 21-01

Desired Future Conditions for the Ogallala, Edwards-Trinity (High Plains), and Dockum Aquifers in Groundwater Management Area 2

WHEREAS, Groundwater Conservation Districts (GCDs) located within or partially within Groundwater Management Area 2 (GMA 2) are required under Chapter 36.108, Texas Water Code to conduct joint planning and designate the Desired Future Conditions of aquifers within GMA 2 and;

WHEREAS, the Board Presidents or their Designated Representatives of GCDs in GMA 2 have met in various meetings and conducted joint planning in accordance with §36.108, Texas Water Code since September 2010; and

WHEREAS, the GMA 2 committee has received and considered Groundwater Availability Model runs and other technical advice regarding local aquifers, hydrology, geology, recharge characteristics, the nine factors set forth in §36.108(d) of the Texas Water Code, local groundwater demands and usage, population projections, total water supply and quality of water supply available from all aquifers within the respective GCDs, regional water plan water management strategies, ground and surface water interactions, that affect groundwater conditions through the year 2070; and

WHEREAS, the member GCDs of GMA 2, having given proper and timely notice, held an open meeting on March 25, 2021 at a remote meeting via Zoom, to vote to adopt proposed Desired Future Conditions for the Ogallala, Edwards-Trinity (High Plains), and Dockum aquifers within the boundaries of GMA 2; and

WHEREAS, the member GCDs in which the Ogallala, Edwards-Trinity (High Plains), and Dockum aquifers are relevant for joint planning purposes held open meetings within each said district between April 29, 2021 and July 13, 2021 to take public comment on the proposed DFCs for that district; and

WHEREAS on this day of August 17, 2021, at an open meeting duly noticed and held in accordance with law at the offices of High Plains Water District located at 2930 Avenue Q, Lubbock, Texas, 79411, having considered at this meeting comments submitted to the individual districts during the comment period and at this meeting, have voted, **6 districts in favor, 1 district absent**, to adopt the following DFCs for in the following counties and districts through the year 2080 as follows:

- A GMA 2-wide average drawdown of 28 feet between 2013 and 2080 for the Ogallala and Edwards-Trinity (High Plains) aquifers
- A GMA 2-wide average drawdown of 31 feet between 2013 and 2080 for the Dockum Aquifer

NOW THEREFORE BE IT RESOLVED, that Groundwater Management Area 2 does hereby document, record, and confirm the above-described Desired Future Conditions for the Ogallala, Edwards-Trinity (High Plains), and Dockum Aquifer which were adopted by vote of the following Designated Representatives of Groundwater Conservation Districts present and voting on August 17, 2021:

Absent

for Garza County UWCD

 _____
for High Plains UWCD #1

 _____
for Llano Estacado UWCD

 _____
for Mesa UWCD

 _____
for Permian Basin UWCD

 _____
for Sandy Land UWCD

 _____
for South Plains UWCD

Groundwater Management Area 2 Resolution 21-02

Declaration that the Edwards-Trinity (Plateau) and Pecos Valley Aquifers Are Not Relevant for Purposes of Joint Planning in Groundwater Management Area 2

WHEREAS, Groundwater Conservation Districts (GCDs) located within or partially within Groundwater Management Area 2 (GMA 2) are required under Chapter 36.108, Texas Water Code to conduct joint planning and designate the Desired Future Conditions of aquifers within GMA 2 and;

WHEREAS, the Board Presidents or their Designated Representatives of GCDs in GMA 2 have met in various meetings and conducted joint planning in accordance with §36.108, Texas Water Code since September 2010; and

WHEREAS, the GMA 2 committee has received and considered Groundwater Availability Model runs and other technical advice regarding local aquifers, hydrology, geology, recharge characteristics, the nine factors set forth in §36.108(d) of the Texas Water Code, local groundwater demands and usage, population projections, total water supply and quality of water supply available from all aquifers within the respective GCDs, regional water plan water management strategies, ground and surface water interactions, that affect groundwater conditions through the year 2070; and

WHEREAS on this day of August 17, 2021, at an open meeting duly noticed and held in accordance with law at the offices of High Plains Water District located at 2930 Avenue Q, Lubbock, Texas, 79411 the GCDs within GMA 2, and voted to adopt proposed Desired Future Conditions for the aquifers of the GMA; and

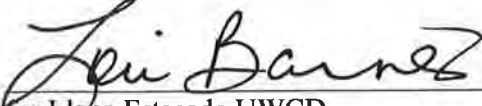

WHEREAS at said meeting held on August 17, 2021, the GCDs within GMA2 voted, upon motion made and seconded, **6 districts in favor, 1 district absent**, to declare the Edwards-Trinity (Plateau) and Pecos Valley aquifers not relevant for purposes of joint planning pursuant to Section 36.108 of the Texas Water Code and therefore not requiring the establishment of DFCs by GMA 2, nor the determination by the Texas Water Development Board (TWDB) of Modeled Available Groundwater (MAGs) for those aquifers in GMA 2,

NOW THEREFORE BE IT RESOLVED, that Groundwater Management Area 2 does hereby document, record, and confirm the above declaration that the Edwards-Trinity (Plateau) and Pecos Valley aquifers are not relevant for purposes of joint planning and therefore not requiring the establishment of DFCs by GMA 2, nor the determination by the Texas Water Development Board (TWDB) of Modeled Available Groundwater (MAGs) for those aquifers in GMA 2, approved by the following votes of the designated representatives of Groundwater Conservation Districts in GMA 2:

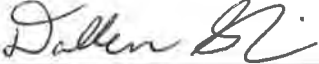

Absent

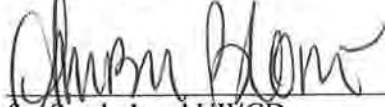

for Garza County UWCD

for High Plains UWCD #1

for Llano Estacado UWCD

for Mesa UWCD

for Permian Basin UWCD

for Sandy Land UWCD
